CryptoVerif:
A Computationally Sound Mechanized Prover for Cryptographic Protocols

Bruno Blanchet

CNRS, École Normale Supérieure, INRIA, Paris

September 2009
Introduction

Two models for security protocols:

- **Computational model:**
  - messages are bitstrings
  - cryptographic primitives are functions from bitstrings to bitstrings
  - the adversary is a probabilistic polynomial-time Turing machine

Proofs are done manually.

- **Formal model** (so-called “Dolev-Yao model”):
  - cryptographic primitives are ideal blackboxes
  - messages are terms built from the cryptographic primitives
  - the adversary is restricted to use only the primitives

Proofs can be done automatically.

Our goal: achieve **automatic provability** under the realistic **computational assumptions**.
Introduction

Two approaches for the automatic proof of cryptographic protocols in a computational model:

- **Indirect approach:**
  1) Make a Dolev-Yao proof.
  2) Use a theorem that shows the soundness of the Dolev-Yao approach with respect to the computational model.
  Pioneered by Abadi and Rogaway; pursued by many others.

- **Direct approach:**
  Design automatic tools for proving protocols in a computational model.
  Approach pioneered by Laud.
Advantages and drawbacks

The indirect approach allows more reuse of previous work, but it has limitations:

- **Hypotheses** have to be added to make sure that the computational and Dolev-Yao models coincide.

- The **allowed cryptographic primitives** are often limited, and only ideal, not very practical primitives can be used.

- Using the Dolev-Yao model is actually a (big) **detour**; The computational definitions of primitives fit the computational security properties to prove. They do not fit the Dolev-Yao model.

We decided to focus on the direct approach.
We have implemented an automatic prover CryptoVerif:

- proves secrecy and correspondence (including authentication) properties.
- provides a generic method for specifying properties of cryptographic primitives which handles MACs (message authentication codes), symmetric encryption, public-key encryption, signatures, hash functions, ... 
- works for \( N \) sessions (polynomial in the security parameter), with an active adversary.
- gives a bound on the probability of an attack (exact security).
Produced proofs

We use Shoup’s and Bellare&Rogaway’s game hopping method.

The proof is a sequence of games:

- The first game is the real protocol.
- One goes from one game to the next by syntactic transformations or by applying the definition of security of a cryptographic primitive. Between consecutive games, the difference of probability of success of an attack is negligible.
- The last game is “ideal”: the security property is obvious from the form of the game. (The advantage of the adversary is typically 0 for this game.)
Input and output of the tool

1. Prepare the input file containing
   - the specification of the protocol to study (initial game),
   - the security assumptions on the cryptographic primitives,
   - the security properties to prove.

2. Run CryptoVerif

3. CryptoVerif outputs
   - the sequence of games that leads to the proof,
   - a succinct explanation of the transformations performed between games,
   - an upper bound of the probability of success of an attack.
Process calculus for games

Games are formalized in a process calculus:

- It is adapted from the pi calculus.
- The semantics is purely probabilistic (no non-determinism).
- All processes run in polynomial time:
  - polynomial number of copies of processes,
  - length of messages on channels bounded by polynomials.

This calculus is inspired by:

- the calculus of [Lincoln, Mitchell, Mitchell, Scedrov, 1998],
- the calculus of [Laud, 2005].
Example

\[ A \rightarrow B : e = \{ k' \}_k, \text{mac}(e, mk) \quad k' \text{ fresh} \]

A sends to B a fresh key \( k' \) encrypted under authenticated encryption, implemented as encrypt-then-MAC.

\( k' \) should remain secret.
Example (initialization)

$A \rightarrow B : e = \{k\}_k, \text{mac}(e, mk) \quad k'$ fresh

$Q_0 = \text{start}(); \textbf{new } r : \text{keyseed}; \textbf{let } k : \text{key} = \text{kgen}(r) \textbf{ in }$

$\textbf{new } r' : \text{mkeyseed}; \textbf{let } mk : \text{mkey} = \text{mkgen}(r') \textbf{ in } \overline{c}; (Q_A \mid Q_B)$

Initialization of keys:

1. The process $Q_0$ waits for a message on channel $\text{start}$ to start running. The adversary triggers this process.

2. $Q_0$ generates encryption and MAC keys, $k$ and $mk$ respectively, using the key generation algorithms $kgen$ and $mkgen$.

3. $Q_0$ returns control to the adversary by the output $\overline{c}$. $Q_A$ and $Q_B$ represent the actions of $A$ and $B$ (see next slides).
Example (role of $A$)

$A \rightarrow B : e = \{k'\}_k, \text{mac}(e, mk) \quad k'$ fresh

$$Q_A = !^{i \leq n}c_A(); \textbf{new} \ k' : \text{key}; \textbf{new} \ r'' : \text{coins};$$

$$\text{let } e : \text{bitstring} = \text{enc}(k2b(k'), k, r'') \textbf{ in}$$

$$\overline{c_A} \langle e, \text{mac}(e, mk) \rangle$$

Role of $A$:

1. $!^{i \leq n}$ represents $n$ copies, indexed by $i \in [1, n]$
   The protocol can be run $n$ times (polynomial in the security parameter).
2. The process is triggered when a message is sent on $c_A$ by the adversary.
3. The process chooses a fresh key $k'$ and sends the message on channel $c_A$. 
Example (role of $B$)

$$A \rightarrow B : e = \{k\}'_k, \text{mac}(e, mk) \quad k' \text{ fresh}$$

$$Q_B = !^{i' \leq n} c_B(e' : \text{bitstring}, ma : \text{macstring});$$
$\text{if } \text{verify}(e', mk, ma) \text{ then}$

$$\text{let } i_\bot(k2b(k'')) = \text{dec}(e', k) \text{ in } c_B\langle \rangle$$

Role of $B$:
1. $n$ copies, as for $Q_A$.
2. The process $Q_B$ waits for the message on channel $c_B$.
3. It verifies the MAC, decrypts, and stores the key in $k''$. 
Example (summary)

\[ A \rightarrow B : e = \{k'\}_k, \text{mac}(e, mk) \quad k' \text{ fresh} \]

\[
Q_0 = \text{start()} ; \text{new } r : \text{keyseed} ; \text{let } k : \text{key} = \text{kgen}(r) \text{ in }
\quad \text{new } r' : m\text{keyseed} ; \text{let } mk : m\text{key} = \text{mkgen}(r') \text{ in } \overline{c}() ; (Q_A | Q_B)
\]

\[
Q_A = i \leq n \text{c}_A() ; \text{new } k' : \text{key} ; \text{new } r'' : \text{coins} ;
\quad \text{let } e : \text{bitstring} = \text{enc}(k2b(k'), k, r'') \text{ in }
\quad \overline{c}_A\langle e, \text{mac}(e, mk) \rangle
\]

\[
Q_B = i' \leq n \text{c}_B(e' : \text{bitstring}, ma : \text{macstring}) ;
\quad \text{if verify}(e', mk, ma) \text{ then }
\quad \text{let } i_{\bot}(k2b(k'')) = \text{dec}(e', k) \text{ in } \overline{c}_B() \rangle
\]
Security assumptions on primitives

The most frequent cryptographic primitives are already specified in a library. The user can use them without redefining them.

In the example:

- The MAC is **UF-CMA** (unforgeable under chosen message attacks). An adversary that has access to the MAC and verification oracles has a negligible probability of forging a MAC (for a message on which the MAC oracle has not been called).
Security assumptions on primitives

The most frequent cryptographic primitives are already specified in a library. The user can use them without redefining them.

In the example:

- The MAC is UF-CMA (unforgeable under chosen message attacks). An adversary that has access to the MAC and verification oracles has a negligible probability of forging a MAC (for a message on which the MAC oracle has not been called).

- The encryption is IND-CPA (indistinguishable under chosen plaintext attacks). An adversary has a negligible probability of distinguishing the encryption of two messages of the same length.
Security assumptions on primitives

The most frequent cryptographic primitives are already specified in a library. The user can use them without redefining them.

In the example:

- The MAC is **UF-CMA** (unforgeable under chosen message attacks). An adversary that has access to the MAC and verification oracles has a negligible probability of forging a MAC (for a message on which the MAC oracle has not been called).
- The encryption is **IND-CPA** (indistinguishable under chosen plaintext attacks). An adversary has a negligible probability of distinguishing the encryption of two messages of the same length.
- All keys have the same length: \( \forall y \in \text{key} ; Z(k2b(y)) = Z_k \).
In the example:

- **One-session secrecy** of $k''$: each $k''$ is indistinguishable from a random number.
- **Secrecy** of $k''$: the $k''$ are indistinguishable from independent random numbers.
Demo

Demo
Process calculus for games: terms

\[ M ::= \quad \text{terms} \]
\[ x, y, z, x[M_1, \ldots, M_n] \quad \text{variable} \]
\[ f(M_1, \ldots, M_n) \quad \text{function application} \]

Function symbols \( f \) correspond to functions computable by polynomial-time deterministic Turing machines.
Process calculus for games: processes

\[ Q ::= \]
\[
0
\]
\[
Q \mid Q'
\]
\[
!i \leq N Q
\]
\[
\text{newChannel } c; Q
\]
\[
c(x_1 : T_1, \ldots, x_m : T_m); P
\]

\[ P ::= \]
\[
\overline{c}(M_1, \ldots, M_m); Q
\]
\[
\text{new } x : T; P
\]
\[
\text{let } x : T = M \text{ in } P
\]
\[
\text{if } M \text{ then } P \text{ else } P'
\]
\[
\text{find } j \leq N \text{ such that } \text{defined}(x[j], \ldots) \wedge M \text{ then } P \text{ else } P'

assignment

conditional

array lookup
Arrays

Arrays replace lists often used in cryptographic proofs.

They avoid the need for explicit list insertion instructions, which would be hard to guess for an automatic tool.

A variable defined under a replication is implicitly an array:

\[ Q_A = !i \leq n c_A(); \text{new } k'[i] : \text{key}; \text{new } r''[i] : \text{coins}; \]

\[
\text{let } e[i] : \text{bitstring} = \text{enc}(k2b(k'[i]), k, r''[i]) \text{ in }
\]

\[ \overline{c_A} \langle e[i], \text{mac}(e[i], mk) \rangle \]

Requirements:

- Only variables with the current indices can be assigned.
- Variables may be defined at several places, but only one definition can be executed for the same indices.

(if ... then let \( x = M \) in \( P \) else let \( x = M' \) in \( P' \) is ok)

So each array cell can be assigned at most once.
Arrays (continued)

find performs an array lookup:

\[ i \leq N \ldots \text{let } x = M \text{ in } P \]
\[ | \neg i' \leq N' c(y : T) \text{find } j \leq N \text{ such that defined}(x[j]) \land y = x[j] \text{ then } \ldots \]

Note that find is here used outside the scope of x.

This is the only way of getting access to values of variables in other sessions.

When several array elements satisfy the condition of the find, the returned index is chosen randomly, with uniform probability.
Indistinguishability as observational equivalence

Two processes (games) $Q_1$, $Q_2$ are observationally equivalent when the adversary has a negligible probability of distinguishing them:

$$Q_1 \approx Q_2$$

In the formal definition, the adversary is represented by an acceptable evaluation context $C ::= [] \mid C \mid Q \mid Q \mid C \mid \text{newChannel} \ c; C$.

- Observational equivalence is an equivalence relation.
- It is contextual: $Q_1 \approx Q_2$ implies $C[Q_1] \approx C[Q_2]$ where $C$ is any acceptable evaluation context.
We transform a game $G_0$ into an observationally equivalent one using:

- **observational equivalences** $L \approx R$ given as axioms and that come from security assumptions on primitives. These equivalences are used inside a context:
  
  $$G_1 \approx C[L] \approx C[R] \approx G_2$$
  
- **syntactical transformations**: simplification, expansion of assignments, ...

We obtain a sequence of games $G_0 \approx G_1 \approx \ldots \approx G_m$, which implies $G_0 \approx G_m$.

If some equivalence or trace property holds with overwhelming probability in $G_m$, then it also holds with overwhelming probability in $G_0$.
MACs: security definition

A MAC scheme:

- (Randomized) key generation function \( \text{mkgen} \).
- MAC function \( \text{mac}(m, k) \) takes as input a message \( m \) and a key \( k \).
- Verification function \( \text{verify}(m, k, t) \) such that
  \[
  \text{verify}(m, k, \text{mac}(m, k)) = \text{true}.
  \]

A MAC guarantees the integrity and authenticity of the message because only someone who knows the secret key can build the mac.

More formally, an adversary \( A \) that has oracle access to \( \text{mac} \) and \( \text{verify} \) has a negligible probability of forging a MAC (UF-CMA):

\[
\Pr[\text{verify}(m, k, t) \mid k \leftarrow \text{mkgen}; (m, t) \leftarrow A^\text{mac(.)-\text{verify}(\cdot,\cdot,\cdot)}] \]

is negligible, when the adversary \( A \) has not called the \( \text{mac} \) oracle on message \( m \).
MACs: intuitive implementation

By the previous definition, up to negligible probability,
- the adversary cannot forge a correct MAC
- so when verifying a MAC with $\text{verify}(m, k, t)$ and $k \leftarrow \text{mkgen}$ is used only for generating and verifying MACs, the verification can succeed only if $m$ is in the list (array) of messages whose $\text{mac}$ has been computed by the protocol
- so we can replace a call to $\text{verify}$ with an array lookup:
  if the call to $\text{mac}$ is $\text{mac}(x, k)$, we replace $\text{verify}(m, k, t)$ with

$$\text{find } j \leq N \text{ such that defined}(x[j]) \land \ (m = x[j]) \land \text{verify}(m, k, t) \text{ then true else false}$$
MACs: formal implementation

```
verify(m, mkgen(r), mac(m, mkgen(r))) = true

!^N'' new r : mkeyseed; ( 
  !^N(x : bitstring) → mac(x, mkgen(r)),
  !^N'(m : bitstring, t : macstring) → verify(m, mkgen(r), t))
≈
!^N'' new r : mkeyseed; ( 
  !^N(x : bitstring) → mac(x, mkgen(r)),
  !^N'(m : bitstring, t : macstring) →
    find j ≤ N such that defined(x[j]) ∧ (m = x[j]) ∧ 
    verify(m, mkgen(r), t) then true else false)
```

The prover understands such specifications of primitives. They can be reused in the proof of many protocols.
**MACs: formal implementation**

\[
\text{verify}(m, \text{mkgen}(r), \text{mac}(m, \text{mkgen}(r))) = \text{true}
\]

\[\!^N'' \textbf{new} \ r : \text{mkeyseed}; (\]
\[\!^N(x : \text{bitstring}) \rightarrow \text{mac}(x, \text{mkgen}(r)),\]
\[\!^N'(m : \text{bitstring}, t : \text{macstring}) \rightarrow \text{verify}(m, \text{mkgen}(r), t)\]
\[\approx\]

\[\!^N'' \textbf{new} \ r : \text{mkeyseed}; (\]
\[\!^N(x : \text{bitstring}) \rightarrow \text{mac}'(x, \text{mkgen}'(r)),\]
\[\!^N'(m : \text{bitstring}, t : \text{macstring}) \rightarrow \]
\[\textbf{find} \ j \leq N \ \textbf{such that defined}(x[j]) \land (m = x[j]) \land \]
\[\text{verify}'(m, \text{mkgen}'(r), t) \ \text{then true else false}\]

The prover understands such specifications of primitives.
They can be reused in the proof of many protocols.
MACs: formal implementation

The prover applies the previous rule automatically in any (polynomial-time) context, perhaps containing several occurrences of *mac* and of *verify*:

- Each occurrence of *mac* is replaced with *mac*'.
- Each occurrence of *verify* is replaced with a **find** that looks in all arrays of computed MACs (one array for each occurrence of function *mac*).
A strongly unforgeable under chosen message attacks (SUF-CMA) MAC is defined as follows:

\[
\Pr[\text{verify}(m, k, t) \mid k \xleftarrow{R} \text{mkgen}; (m, t) \leftarrow A^{\text{mac}(\cdot, k), \text{verify}(\cdot, k, \cdot)}] \]

is negligible, when \( t \) is not the result of calling the MAC oracle \( \text{mac}(\cdot, k) \) on \( m \).

Represent it in the CryptoVerif formalism.
Exercise

A **signature scheme** consists of

- a key generation algorithm \((pk, sk) \leftarrow kgen\)
- a signature algorithm \(\text{sign}(m, sk)\)
- a verification algorithm \(\text{verify}(m, pk, s)\)

such that \(\text{verify}(m, pk, \text{sign}(m, sk)) = 1\).

A signature scheme is unforgeable under chosen message attacks (UF-CMA) if and only if

\[
\Pr[\text{verify}(m, pk, s) \mid (pk, sk) \leftarrow kgen; (m, s) \leftarrow A^{\text{sign}(\cdot, sk)}(pk)]
\]

is negligible, when the adversary \(A\) has not called the \(\text{sign}(\cdot, sk)\) oracle on message \(m\).

Represent it in the CryptoVerif formalism.
IND-CPA symmetric encryption

We consider a probabilistic, length-revealing encryption scheme that satisfies INDistinguishability under Chosen Plaintext Attacks (IND-CPA).

\[
dec(\text{enc}(m, k\text{gen}(r), r'), k\text{gen}(r)) = i_{\perp} (m)
\]

\[
!^{N'} \text{new } r : \text{keyseed}; !^{N} (x : \text{bitstring}) \rightarrow
\]
\[
\text{new } r' : \text{coins}; \text{enc}(x, k\text{gen}(r), r')
\]
\[
\approx
\]
\[
!^{N'} \text{new } r : \text{keyseed}; !^{N} (x : \text{bitstring}) \rightarrow
\]
\[
\text{new } r' : \text{coins}; \text{enc}'(\text{Z}(x), k\text{gen}'(r), r')
\]

\(\text{Z}(x)\) is the bitstring of the same length as \(x\) containing only zeroes (for all \(x : \text{nonce}, \text{Z}(x) = \text{Znonce}, \ldots\)).
A symmetric encryption scheme satisfies ciphertext integrity (INT-CTXT) if and only if

$$\Pr[\text{dec}(c, k) \neq \bot \mid k \xleftarrow{\$} \text{kgen}; c \leftarrow \mathcal{A}^{\text{enc}(.,k),\text{dec}(.,k)\neq\bot}]$$

is negligible, when $c$ is not the result of a call to the $\text{enc}(., k)$ oracle. Represent it in the CryptoVerif formalism.
Exercise

A public-key encryption scheme consists of

- a key generation algorithm $(pk, sk) \leftarrow kgen$
- a probabilistic encryption algorithm $enc(m, pk)$
- a decryption algorithm $dec(m, sk)$

such that $dec(enc(m, pk), sk) = m$.

A public-key encryption scheme is indistinguishable under adaptive chosen-ciphertext attacks (IND-CCA2) if and only if

$$2 \Pr \left[ b \leftarrow \{0, 1\}; (pk, sk) \leftarrow kgen; 
\left. b' \leftarrow A^{\text{enc}(LR(\ldots, b), pk), \text{dec}(\ldots, sk)}(pk) : b' = b \right] - 1$$

is negligible, where $A$ never calls the $dec(., sk)$ oracle on the result of the $enc(LR(., ., b), pk)$ oracle. Represent it in the CryptoVerif formalism.
Syntactic transformations: expansion of assignments

Expansion of assignments: replacing a variable with its value. (Not completely trivial because of array references.)

Example

If $mk$ is defined by

$$\textbf{let} \; mk = mkgen(r')$$

and there are no array references to $mk$, then $mk$ is replaced with $mkgen(r')$ in the game and the definition of $mf$ is removed.
Syntactic transformations: single assignment renaming

**Single assignment renaming:** when a variable is assigned at several places, rename it with a distinct name for each assignment. (Not completely trivial because of array references.)

**Example**

```plaintext
start(); new r_A : T_r; let k_A = kgen(r_A) in
  new r_B : T_r; let k_B = kgen(r_B) in \overline{c}\langle\rangle; (Q_K \mid Q_S)
Q_K = \forall i \leq n. c(h : T_h, k : T_k)
  if h = A then let k' = k_A else
  if h = B then let k' = k_B else let k' = k
Q_S = \forall i' \leq n'. c'(h' : T_h);
  find j \leq n such that defined(h[j], k'[j]) ∧ h' = h[j] then P_1(k'[j])
else P_2
```
Syntactic transformations: single assignment renaming

Single assignment renaming: when a variable is assigned at several places, rename it with a distinct name for each assignment.
(Not completely trivial because of array references.)

Example

\begin{verbatim}
start(); new r_A : T_r; let k_A = kgen(r_A) in
    new r_B : T_r; let k_B = kgen(r_B) in \text{c}(\langle\rangle; (Q_K | Q_S)
Q_K = \Pi_{i \leq n} c(h : T_h, k : T_k)
    if h = A then let k_1' = k_A else
    if h = B then let k_2' = k_B else let k_3' = k
Q_S = \Pi_{i' \leq n'} c'(h' : T_h);
    find j \leq n suchthat defined(h[j], k_1'[j]) \land h' = h[j] then P_1(k_1'[j])
    orfind j \leq n suchthat defined(h[j], k_2'[j]) \land h' = h[j] then P_1(k_2'[j])
    orfind j \leq n suchthat defined(h[j], k_3'[j]) \land h' = h[j] then P_1(k_3'[j])
else P_2
\end{verbatim}
Syntactic transformations: move new

**Move new**: move restrictions downwards in the game as much as possible, when there is no array reference to them.

(Moving `new x : T` under a `if` or a `find` duplicates it. A subsequent single assignment renaming will distinguish cases.)

**Example**

```
new x : nonce; if c then P₁ else P₂
```

becomes

```
if c then new x : nonce; P₁ else new x : nonce; P₂
```
Simplification and elimination of collisions

- CryptoVerif collects equalities that come from:
  - Assignments: let $x = M$ in $P$ implies that $x = M$ in $P$
  - Tests: if $M = N$ then $P$ implies that $M = N$ in $P$
  - Definitions of cryptographic primitives
    - When a find guarantees that $x[j]$ is defined, equalities that hold at definition of $x$ also hold under the find (after substituting $j$ for the array indices at the definition of $x$)
  - Elimination of collisions: if $x$ is created by new $x : T$, $x[i] = x[j]$ implies $i = j$, up to negligible probability (when $T$ is large)

- These equalities are combined to simplify terms.

- When terms can be simplified, processes are simplified accordingly. For instance:
  - If $M$ simplifies to true, then if $M$ then $P_1$ else $P_2$ simplifies $P_1$.
  - If a condition of find simplifies to false, then the corresponding branch is removed.
Proof of security properties: one-session secrecy

One-session secrecy: the adversary cannot distinguish any of the secrets from a random number with one test query.

Criterion for proving one-session secrecy of $x$:
$x$ is defined by **new** $x[i] : T$ and there is a set of variables $S$ such that only variables in $S$ depend on $x$.
The output messages and the control-flow do not depend on $x$. 
Proof of security properties: secrecy

**Secrecy**: the adversary cannot distinguish the secrets from independent random numbers with several test queries.

**Criterion for proving secrecy of** $x$: same as one-session secrecy, plus $x[i]$ and $x[i']$ do not come from the same copy of the same restriction when $i \neq i'$. 
Proof strategy: advice

- One tries to execute each transformation given by the definition of a cryptographic primitive.
- When it fails, it tries to analyze why the transformation failed, and suggests syntactic transformations that could make it work.
- One tries to execute these syntactic transformations. (If they fail, they may also suggest other syntactic transformations, which are then executed.)
- We retry the cryptographic transformation, and so on.
Proof of the example: initial game

\[ Q_0 = \text{start}(); \textbf{new} \ r : \text{keyseed}; \textbf{let} \ k : \text{key} = \text{kgen}(r) \ \textbf{in} \]
\[ \textbf{new} \ r' : \text{mkeyseed}; \textbf{let} \ mk : \text{mkey} = \text{mkgen}(r') \ \textbf{in} \ c\langle\rangle; (Q_A | Q_B) \]

\[ Q_A = !i^{\leq n} c_A(); \textbf{new} \ k' : \text{key}; \textbf{new} \ r'' : \text{coins}; \]
\[ \textbf{let} \ e : \text{bitstring} = \text{enc}(k2b(k'), k, r'') \ \textbf{in} \]
\[ c_A\langle e, \text{mac}(e, mk)\rangle \]

\[ Q_B = !i'^{\leq n} c_B(e' : \text{bitstring}, ma : \text{macstring}); \]
\[ \textbf{if} \ \text{verify}(e', mk, ma) \ \textbf{then} \]
\[ \textbf{let} \ i_{\bot}(k2b(k'')) = \text{dec}(e', k) \ \textbf{in} \ c_B\langle\rangle \]
Proof of the example: remove assignments \textit{mk}

\[
Q_0 = \text{start}(); \textbf{new } r : \text{keyseed}; \textbf{let } k : \text{key} = \text{kgen}(r) \textbf{ in } \\
\textbf{new } r' : \text{mkeyseed}; \overline{c}(); (Q_A \mid Q_B)
\]

\[
Q_A = !^{i \leq n} c_A(); \textbf{new } k' : \text{key}; \textbf{new } r'' : \text{coins}; \\
\textbf{let } e : \text{bitstring} = \text{enc}(k2b(k'), k, r'') \textbf{ in } \\
\overline{c_A}\langle e, \text{mac}(e, \text{mkgen}(r')) \rangle
\]

\[
Q_B = !^{i' \leq n} c_B(e' : \text{bitstring}, ma : \text{macstring}); \\
\textbf{if } \text{verify}(e', \text{mkgen}(r'), ma) \textbf{ then } \\
\textbf{let } i_\perp(k2b(k'')) = \text{dec}(e', k) \textbf{ in } \overline{c_B}\langle \rangle
\]
Proof of the example: security of the MAC

\[ Q_0 = \text{start}(); \textbf{new} \ r : \text{keyseed}; \textbf{let} \ k : \text{key} = \text{kgen}(r) \ \textbf{in} \]
\[ \textbf{new} \ r' : \text{mkeyseed}; \overline{c}(); (Q_A \ | \ Q_B) \]

\[ Q_A = \neg i \leq n c_A(); \textbf{new} \ k' : \text{key}; \textbf{new} \ r'' : \text{coins}; \]
\[ \textbf{let} \ e : \text{bitstring} = \text{enc}(k2b(k'), k, r'') \ \textbf{in} \]
\[ \overline{c_A}\langle e, \text{mac'}(e, \text{mkgen'}(r'))\rangle \]

\[ Q_B = \neg i' \leq n c_B(e' : \text{bitstring}, ma : \text{macstring}); \]
\[ \textbf{find} \ j \leq n \ \text{such that} \ \text{defined}(e[j]) \wedge e' = e[j] \wedge \]
\[ \text{verify'}(e', \text{mkgen'}(r'), ma) \ \textbf{then} \]
\[ \textbf{let} \ i_{\bot}(k2b(k'')) = \text{dec}(e', k) \ \textbf{in} \ \overline{c_B}\langle \rangle \]
Proof of the example: simplify

\[ Q_0 = \text{start}(); \textbf{new} r : \text{keyseed}; \textbf{let} k : \text{key} = kgen(r) \textbf{ in} \]
\[ \textbf{new} r' : \text{mkeyseed}; \overline{c}(); (Q_A | Q_B) \]

\[ Q_A = !^{i \leq n} c_A(); \textbf{new} k' : \text{key}; \textbf{new} r'' : \text{coins}; \]
\[ \textbf{let} e : \text{bitstring} = \text{enc}(k2b(k'), k, r'') \textbf{ in} \]
\[ \overline{c_A}\langle e, \text{mac}'(e, \text{mkgen}'(r')) \rangle \]

\[ Q_B = !^{i' \leq n} c_B(e' : \text{bitstring}, ma : \text{macstring}); \]
\[ \textbf{find} j \leq n \textbf{ such that} \textbf{defined}(e[j]) \land e' = e[j] \land \]
\[ \text{verify}'(e', \text{mkgen}'(r'), ma) \textbf{ then} \]
\[ \textbf{let} k'' = k'[j] \textbf{ in} \overline{c_B}\langle \rangle \]

\[ \text{dec}(e', k) = \text{dec}(\text{enc}(k2b(k'[j]), k, r''[j]), k) = i_{\bot}(k2b(k'[j])) \]
Proof of the example: remove assignments $k$

$$Q_0 = \text{start}(); \textbf{new } r : \text{keyseed}; \textbf{new } r' : \text{mkeyseed}; \overline{c}(); (Q_A \mid Q_B)$$

$$Q_A = \!^i \leq^n c_A(); \textbf{new } k' : \text{key}; \textbf{new } r'' : \text{coins};$$

$$\textbf{let } e : \text{bitstring} = \text{enc}(k2b(k'), \text{kgen}(r), r'') \text{ in }$$

$$\overline{c_A}(e, \text{mac'}(e, \text{mkgen'}(r')))$$

$$Q_B = \!^{i'} \leq^n c_B(e' : \text{bitstring}, ma : \text{macstring});$$

$$\textbf{find } j \leq n \text{ such that } \text{defined}(e[j]) \wedge e' = e[j] \wedge$$

$$\text{verify'}(e', \text{mkgen'}(r'), ma) \textbf{ then }$$

$$\textbf{let } k'' = k'[j] \textbf{ in } \overline{c_B}()$$
Proof of the example: security of the encryption

\[ Q_0 = \text{start}(); \textbf{new} \ r : \text{keyseed}; \textbf{new} \ r' : \text{mkeyseed}; \overline{c}\langle \rangle; (Q_A \mid Q_B) \]

\[ Q_A =!^{i \leq n}c_A(); \textbf{new} \ k' : \text{key}; \textbf{new} \ r'' : \text{coins}; \]
\[ \textbf{let} \ e : \text{bitstring} = \text{enc}'(Z(k2b(k'))), kgen'(r), r'') \textbf{in} \]
\[ \overline{c_A}\langle e, \text{mac}'(e, \text{mkgen}'(r'))\rangle \]

\[ Q_B =!^{i' \leq n}c_B(e' : \text{bitstring}, ma : \text{macstring}); \]
\[ \textbf{find} \ j \leq n \text{ suchthat defined}(e[j]) \wedge e' = e[j] \wedge \]
\[ \text{verify}'(e', \text{mkgen}'(r'), ma) \textbf{then} \]
\[ \textbf{let} \ k'' = k'[j] \textbf{in} \overline{c_B}\langle \rangle \]
Proof of the example: simplify

\[ Q_0 = \text{start}(); \textbf{new} \ r : \text{keyseed}; \textbf{new} \ r' : \text{mkeyseed}; \overline{c}(); (Q_A \mid Q_B) \]

\text{verify}'(e', \text{mkgen}'(r'), ma) \textbf{ then } \\
\text{let } k'' &= k'[j] \textbf{ in } \overline{c_B} \rangle
\end{align*}
\]

\[ Z(k2b(k')) = Z_k \]
Proof of the example: secrecy

\[ Q_0 = \text{start}(); \text{new } r : \text{keyseed}; \text{new } r' : \text{mkeyseed}; \overline{c} \rangle; (Q_A \mid Q_B) \]

\[ Q_A = !^{i \leq n} c_A(); \text{new } k' : \text{key}; \text{new } r'' : \text{coins}; \]
\[ \text{let } e : \text{bitstring} = \text{enc}'(Z_k, kgen'(r), r'') \text{ in} \]
\[ \overline{c_A} \langle e, \text{mac}'(e, mgen'(r')) \rangle \]

\[ Q_B = !^{i' \leq n} c_B(e' : \text{bitstring}, ma : \text{macstring}); \]
\[ \text{find } j \leq n \text{ such that defined}(e[j]) \land e' = e[j] \land \]
\[ \text{verify}'(e', mgen'(r'), ma) \text{ then} \]
\[ \text{let } k'' = k'[j] \text{ in } \overline{c_B} \rangle \]

Preserves the one-session secrecy of \( k'' \) but not its secrecy.
Example of the FDH signature (joint work with D. Pointcheval)

hash hash function (in the random oracle model)
f(pk, m) one-way trapdoor permutation, with inverse invf(sk, m).

We define a signature scheme as follows:

- signature $\text{sign}(m, sk) = \text{invf}(sk, \text{hash}(m))$
- verification $\text{verify}(m, pk, s) = (f(pk, s) = \text{hash}(m))$

Our goal is to show that this signature scheme is UF-CMA (secure against existential forgery under chosen message attacks).
Key generation:

\[ c_{\text{gen}}(); \textbf{new} \ r : \textit{seed}; \textbf{let} \ sk = \text{skgen}(r) \textbf{ in let} \ pk = \text{pkgen}(r) \textbf{ in } c_{\text{gen}}\langle pk \rangle \]

Chooses a random seed uniformly in the set of bit-strings \textit{seed} (consisting of all bit-strings of a certain length), generates a public key \( pk \), a secret key \( sk \), and returns the public key.
Formalizing the security of a signature scheme (2)

Signature:

\[ c_S(m : \text{bitstring}); \overline{c_S(\text{sign}(sk, m))} \]
Formalizing the security of a signature scheme (2)

Signature:

\[ c_S(m : \text{bitstring}); \overline{c_S}\langle \text{sign}(sk, m) \rangle \]

This process can be called at most \( q_S \) times:

\[ \forall i \leq q_S c_S(m : \text{bitstring}); \overline{c_S}\langle \text{sign}(sk, m) \rangle \]
Formalizing the security of a signature scheme (2)

Signature:
\[ c_S(m : \text{bitstring}); \overline{c_S} \langle \text{sign}(sk, m) \rangle \]

This process can be called at most \( q_S \) times:
\[ \forall i \leq q_S c_S(m : \text{bitstring}); \overline{c_S} \langle \text{sign}(sk, m) \rangle \]

In fact, this is an abbreviation for:
\[ \forall i \leq q_S c_S(m[i_S] : \text{bitstring}); \overline{c_S} \langle \text{sign}(sk, m[i_S]) \rangle \]

The variables in repeated oracles are arrays, with one cell for each call, to remember the values used in each oracle call. These arrays are indexed with the call number \( i_S \).
Test:

\[ c_T(m' : \text{bitstring}, s : D); \textbf{if} \ \text{verify}(m', pk, s) \ \textbf{then} \]
\[ \textbf{find} \ j \leq q_S \ \textbf{suchthat defined}(m[j]) \land (m' = m[j]) \]
\[ \textbf{then yield else event forge} \]

If \( s \) is a signature for \( m' \) and the signed message \( m' \) is not contained in the array \( m \) of messages passed to signing oracle, then the signature is a \textbf{forgery}, so we execute \textbf{event forge}.
Formalizing the security of a signature scheme (summary)

The signature and test oracles make sense only after the key generation oracle has been called, hence a sequential composition.

The signature and test oracles are simultaneously available, hence a parallel composition.

\[
c_{gen}(); \; \textbf{new} \; r : \text{seed}; \; \textbf{let} \; sk = \text{skgen}(r) \; \textbf{in} \; \textbf{let} \; pk = \text{pkgen}(r) \; \textbf{in} \; \overline{c_{gen}}(pk)
\]

\[
(i \leq q_S \; c_S \; (m : \text{bitstring}); \; \overline{c_S}(\text{sign}(sk, m))
\]

\[
| \; c_T \; (m' : \text{bitstring}, s : D); \; \textbf{if} \; \text{verify}(m', pk, s) \; \textbf{then} \;
\]

\[
\textbf{find} \; j \leq q_S \; \textbf{such that} \; \text{defined}(m[j]) \; \land \; (m' = m[j])
\]

\[
\textbf{then} \; \text{yield} \; \textbf{else} \; \text{event} \; \text{forge}
\]

The probability of executing event forge in this game is the probability of forging a signature.
Application to the FDH signature scheme

We add a hash oracle because the adversary must be able to call the random oracle (even though it cannot be implemented).

\[
c_{\text{gen}}(); \text{new} \ r : \text{seed}; \text{let} \ sk = \text{skgen}(r) \ \text{in} \ \text{let} \ pk = \text{pkgen}(r) \ \text{in} \ \overline{c_{\text{gen}}}(pk)
\]

\[
(|^{i_H \leq q_H} c_H(x : \text{bitstring}); \ \overline{c_H}(\text{hash}(x))
\]

\[
|^{i_S \leq q_S} c_S(m : \text{bitstring}); \ \overline{c_S}(\text{invf}(sk, \text{hash}(m))
\]

| \ c_T(m' : \text{bitstring}, s : D); \text{if} \ f(pk, s) = \text{hash}(m') \ \text{then}

\text{find} \ j \leq q_S \ \text{such that defined}(m[j]) \land (m' = m[j])

\text{then yield} \ \text{else event} \ \text{forge})

Our goal is to bound the probability that \textbf{event forge} is executed in this game.

This game is given as input to the prover in the syntax above.
FDH: security of a hash function (random oracle model)

A hash function is equivalent to a “random function”: a function that
- returns a new random number when it is called on a new argument,
- and returns the same result when it is called on the same argument.

\[ \forall^n h \ (x : \text{bitstring}) \rightarrow \text{hash}(x) \] [all]

\[ \approx_0 \]

\[ \forall^n h \ (x : \text{bitstring}) \rightarrow \]
- find \( j \leq N \) such that defined \((x[j], r[j]) \land (x = x[j])\)
- then \( r[j] \)
- else new \( r : D; r \)
The adversary inverts \( f \) when, given the public key \( pk = \text{pkgen}(r_0) \) and the image of some \( x_0 \) by \( f_{pk} \), it manages to find \( x_0 \) (without having the trapdoor).

The function \( f \) is **one-way** when the adversary has negligible probability of inverting \( f \).
FDH: one-wayness

\[ \begin{align*}
!^{n_k} & \textbf{new } r : \textit{seed}; ( \\
& ( ) \rightarrow \text{pkgen}(r), \\
!^{n_f} & \textbf{new } y : D; ( \\
& ( ) \rightarrow f(\text{pkgen}(r), y), \\
!^{n_1} & (x : D) \rightarrow (x = y), \\
& ( ) \rightarrow y)) \\
\end{align*} \]

\[ \approx n_k \times n_f \times \text{Succ}_P^{ow}(t + (n_k n_f - 1)t_f + (n_k - 1)t_{\text{pkgen}}) \]

\[ \begin{align*}
!^{n_k} & \textbf{new } r : \textit{seed}; ( \\
& ( ) \rightarrow \text{pkgen}'(r), \\
!^{n_f} & \textbf{new } y : D; ( \\
& ( ) \rightarrow f'(\text{pkgen}'(r), y), \\
!^{n_1} & (x : D) \rightarrow \textbf{if defined}(k) \textbf{ then } x = y \textbf{ else } \text{false}, \\
& ( ) \rightarrow \textbf{let } k : \textit{bitstring} = \textit{mark} \textbf{ in } y) \\
\end{align*} \]
FDH: other properties of one-way trapdoor permutations

invf is the inverse of f:
\[ \forall r : seed, x : D; \text{invf}(\text{skgen}(r), f(\text{pkgen}(r), x)) = x \]

f is injective:
\[ \forall k : key, x : D, x' : D; (f(k, x) = f(k, x')) = (x = x') \]

We can replace a uniformly distributed random number \( y \) with \( f(\text{pkgen}(r), y') \) where \( y' \) is a uniformly distributed random number:

\[
!^{n_k} \text{new } r : seed; ( \\
() \rightarrow \text{pkgen}(r), \\
!^{n_f} \text{new } y : D; ((()) \rightarrow \text{invf}(\text{skgen}(r), y), ((()) \rightarrow y)) \\
\approx_0 \\
!^{n_k} \text{new } r : seed; ( \\
() \rightarrow \text{pkgen}(r), \\
!^{n_f} \text{new } y' : D; ((()) \rightarrow y', ((()) \rightarrow f(\text{pkgen}(r), y')))))
\]
FDH: initial game

\[ c_{\text{gen}}(); \textbf{new} r : \text{seed}; \textbf{let} \ sk = \text{skgen}(r) \ \textbf{in} \ \textbf{let} \ pk = \text{pkgen}(r) \ \textbf{in} \ c_{\text{gen}}\langle pk \rangle; \]

| }
FDH step 1: apply the security of the hash function

Replace each occurrence of hash($M$) with a lookup in the arguments of previous calls to hash.

- If $M$ is found, return the same result as the previous result.
- Otherwise, pick a new random number and return it.

For instance, $c_H\langle\text{hash}(x)\rangle$ is replaced with

\[
\text{find } \text{suchthat defined}(m', r_{30}) \land (x = m') \text{ then } c_H\langle r_{30}\rangle
\]

\[
\text{orfind } @i1 \leq q_S \text{ suchthat defined}(m[@i1], r_{32}@i1) \land (x = m[@i1]) \text{ then } c_H\langle r_{32}@i1\rangle
\]

\[
\text{orfind } @i2 \leq q_H \text{ suchthat defined}(x[@i2], r_{34}@i2) \land (x = x[@i2]) \text{ then } c_H\langle r_{34}@i2\rangle
\]

else

\[
\text{new } r_{34} : D; \ c_H\langle r_{34}\rangle
\]
FDH step 2: simplify

(* forged signature? *)
\(c_T(m' : \text{bitstring}, s : D)\);
find suchthat defined\((m', r_{30}) \land (m' = m')\) then
  if \((f(pk, s) = r_{30})\) then
    find \(j \leq q_S\) suchthat defined\((m[j]) \land (m' = m[j])\) then yield else event forge
  or find \(\oplus i5 \leq q_S\) suchthat defined\((m[\oplus i5], r_{32}[\oplus i5]) \land (m' = m[\oplus i5])\) then
    if \((f(pk, s) = r_{32}[\oplus i5])\) then
      find \(j \leq q_S\) suchthat defined\((m[j]) \land (m' = m[j])\) then yield else event forge
  else
    new \(r_{30} : D;\)
    if \((f(pk, s) = r_{30})\) then
      find \(j \leq q_S\) suchthat defined\((m[j]) \land (m' = m[j])\) then yield else event forge

The red test always succeeds, so the blue part becomes yield.
\(r_{30}\) is never defined in the first branch of find.
FDH step 3: substitute $sk$ with its value

The variable $sk$ is replaced with $skgen(r)$, and the assignment $\textbf{let } sk = skgen(r)$ is removed.
This transformation is advised in order to able to apply the permutation property.
FDH step 4: permutation

(* signature oracle *)
\( \exists s \leq q_S \)
\[ c_S(m : \text{bitstring}); \]
\[ \text{find such that defined}(m', r_{-30}) \land (m = m') \text{ then} \]
\[ c_S \langle \text{invf}(\text{skgen}(r), r_{-30}) \rangle \]
\[ \text{or find } @i_3 \leq q_S \text{ such that defined}(m[@i_3], r_{-32}@i_3) \land (m = m[@i_3]) \text{ then} \]
\[ c_S \langle \text{invf}(\text{skgen}(r), r_{-32}@i_3) \rangle \]
\[ \text{or find } @i_4 \leq q_H \text{ such that defined}(x[@i_4], r_{-34}@i_4) \land (m = x[@i_4]) \text{ then} \]
\[ c_S \langle \text{invf}(\text{skgen}(r), r_{-34}@i_4) \rangle \]
\[ \text{else} \]
\[ \text{new } r_{-32} : D; \]
\[ c_S \langle \text{invf}(\text{skgen}(r), r_{-32}) \rangle \]

\text{new } r_{-i} : D \text{ becomes new } y_{-i} : D, \]
\( \text{invf}(\text{skgen}(r), r_{-i}) \text{ becomes } y_{-i}, \)
\( r_{-i} \text{ becomes } f(\text{pkgen}(r), y_{-i}) \)
FDH step 5: simplify

(* forged signature? *)
\[ c_T(m': \text{bitstring}, s : D); \]
find \( \oplus i_5 \leq q_S \) such that defined \((m[\oplus i_5], r_{32}[\oplus i_5]) \land (m' = m[\oplus i_5]) \) then yield

\[ \text{or find } \oplus i_6 \leq q_H \text{ such that defined } (x[\oplus i_6], r_{34}[\oplus i_6]) \land (m' = x[\oplus i_6]) \text{ then} \]

if \((f(pk, s) = f(pkgen(r), y_{34}[\oplus i_6])) \) then
find \( j \leq q_S \) such that defined \((m[j]) \land (m' = m[j]) \) then yield else event forge
else
new \( y_{30} : D; \)
if \((f(pk, s) = f(pkgen(r), y_{30})) \) then
find \( j \leq q_S \) such that defined \((m[j]) \land (m' = m[j]) \) then yield else event forge

\[ f(pk, s) = f(pkgen(r), y_{-1}) \text{ becomes } s = y_{-1}, \]

knowing \( pk = pkgen(r) \) and the injectivity of \( f: \)
\[ \forall k : \text{key}, x : D, x' : D; (f(k, x) = f(k, x')) = (x = x') \]
FDH step 6: one-wayness

(* forged signature? *)
\[ c_T(m' : \text{bitstring}, s : D); \]
\[ \text{find } @i5 \leq q_S \text{ such that defined}(m[@i5], r_{32}@i5) \land (m' = m[@i5]) \text{ then yield} \]
\[ \text{or find } @i6 \leq q_H \text{ such that defined}(x[@i6], r_{34}@i6) \land (m' = x[@i6]) \text{ then} \]
\[ \text{if } s = y_{34}@i6 \text{ then} \]
\[ \text{find } j \leq q_S \text{ such that defined}(m[j]) \land (m' = m[j]) \text{ then yield else event forge} \]
\[ \text{else} \]
\[ \text{new } y_{30} : D; \]
\[ \text{if } s = y_{30} \text{ then} \]
\[ \text{find } j \leq q_S \text{ such that defined}(m[j]) \land (m' = m[j]) \text{ then yield else event forge} \]

\[ s = y_{i} \text{ becomes find } @j_{i} \leq q_H \text{ such that defined}(k_{i}@j_{i}) \]
\[ \text{then } s = y_{i} \text{ else false,} \]
In hash oracle, \( f(pkgen(r), y_{i}) \) becomes \( f'(pkgen'(r), y_{i}) \),
In signature oracle, \( y_{i} \) becomes \( \text{let } k_{i} : \text{bitstring} = \text{mark in } y_{i}. \)
Difference of probability: \((q_H + q_S + 1)P_{OW}(\text{time})\).
FDH step 7: simplify

(* forged signature? *)
\[ c_T(m' : \text{bitstring}, s : D); \]
\[ \text{find } @i5 \leq q_S \text{ such that defined}(m[@i5], r_{32}@i5) \land (m' = m[@i5]) \text{ then yield} \]
\[ \text{orf} \text{find } @i6 \leq q_H \text{ such that defined}(x[@i6], r_{34}@i6) \land (m' = x[@i6]) \text{ then} \]
\[ \text{find } @j.34 \leq q_S \text{ such that defined}(k_{34}@j.34) \land (@i4@j.34 = @i6) \text{ then} \]
\[ \text{if } s = y.34[@i6] \text{ then} \]
\[ \text{find } j \leq q_S \text{ such that defined}(m[j]) \land (m' = m[j]) \text{ then yield else event forge} \]
\[ \text{else} \]
\[ \text{new } y.30 : D; \]
\[ \text{find } @j.30 \leq q_H \text{ such that defined}(k_{30}@j.30) \text{ then} \]
\[ \text{if } s = y.30 \text{ then} \]
\[ \text{find } j \leq q_S \text{ such that defined}(m[j]) \land (m' = m[j]) \text{ then yield else event forge} \]

The tests in red always succeed, so event forge disappears, which proves the desired property.
FDH step 7: simplify (2)

(*) forged signature? *)

c_T(m' : bitstring, s : D);

\ldots

\textbf{new} \ y_\text{30} : D;
\textbf{find} \ \forall j_\text{30} \leq q_H \text{ suchthat defined}(k_\text{30}@j_\text{30}) \text{ then }
\textbf{if} \ s = y_\text{30} \text{ then }
\textbf{find} \ j \leq q_S \text{ suchthat defined}(m[j]) \land (m' = m[j]) \text{ then yield else event forge}

Definition of k_\text{30}:

\[ \forall s \leq q_S \]

c_S(m : bitstring);
\textbf{find} \ \text{suchthat defined}(m', y_\text{30}) \land (m = m') \text{ then }
\textbf{let} \ k_\text{30} : \text{bitstring} = \text{mark in} \ldots

When k_\text{30}@j_\text{30} is defined, m@j_\text{30} is defined and m@j_\text{30} = m', so the test \ j \leq q_S \text{ suchthat defined}(m[j]) \land (m' = m[j]) succeeds with \ j = @j_\text{30}. 
FDH step 7: simplify (3)

(* forged signature? *)

\( c_T(m' : \text{bitstring}, s : D); \)

\ldots

\textbf{orfind} \(@i6 \leq q_H\) such that \texttt{defined}(x[@i6], r_{34}[@i6]) \land (m' = x[@i6]) \textbf{then}

\textbf{find} \(@j_{34} \leq q_S\) such that \texttt{defined}(k_{34}@j_{34}) \land (@i4[@j_{34}] = @i6) \textbf{then}

\textbf{if} \ s = y_{34}@i6 \textbf{ then}

\textbf{find} \ j \leq q_S \texttt{such that defined}(m[j]) \land (m' = m[j]) \textbf{ then yield else event forge}

Definition of \( k_{34} \):

\( !is \leq qs \)

\( c_S(m : \text{bitstring}); \)

\ldots

\textbf{orfind} \(@i4 \leq q_H\) such that \texttt{defined}(x[@i4], y_{34}@i4)) \land (m = x[@i4]) \textbf{then}

\textbf{let} \ k_{34} : \text{bitstring} = \text{mark in} \ldots

When \( k_{34}@j_{34} \) is defined, \( m[@j_{34}] \) is defined and

\( m[@j_{34}] = x[@i4[@j_{34}]] = x[@i6] = m' \)

so the red test succeeds with \( j = @j_{34} \).
Experiments

Tested on the following protocols (original and corrected versions):
- Otway-Rees (shared-key)
- Yahalom (shared-key)
- Denning-Sacco (public-key)
- Woo-Lam shared-key and public-key
- Needham-Schroeder shared-key and public-key
- Full domain hash signature (with D. Pointcheval)
- Encryption schemes of Bellare-Rogaway’93 (with D. Pointcheval)

Shared-key encryption is implemented as encrypt-then-MAC, using a IND-CPA encryption scheme.
(For Otway-Rees, we also considered a SPRP encryption scheme,
a IND-CPA + INT-CTXT encryption scheme,
a IND-CCA2 + IND-PTXT encryption scheme.)

Public-key encryption is assumed to be IND-CCA2.
We prove secrecy of session keys and correspondence properties.
Results (1)

In most cases, the prover succeeds in proving the desired properties when they hold, and obviously it always fails to prove them when they do not hold.

Only cases in which the prover fails although the property holds:

- Needham-Schroeder public-key when the exchanged key is the nonce $N_A$.
- Needham-Schroeder shared-key: fails to prove that $N_B[i] \neq N_B[i'] - 1$ with overwhelming probability, where $N_B$ is a nonce.
- Showing that the encryption scheme $E(m, r) = f(r) \| H(r) \oplus m \| H'(m, r)$ is IND-CCA2.
Some public-key protocols need manual proofs.
(Give the cryptographic proof steps and single assignment renaming instructions.)

Runtime: 7 ms to 35 s, average: 5 s on a Pentium M 1.8 GHz.

A detailed case study of Kerberos V, with and without its public-key extension PKINIT (AsiaCCS’08, with Aaron D. Jaggard, Andre Scedrov, and Joe-Kai Tsay).

Starts being used by others: Verification of F# implementations, including TLS, by Microsoft Research and the MSR-INRIA lab.
Conclusion

CryptoVerif can automatically prove the security of primitives and protocols.

- The security assumptions are given as observational equivalences (proved manually once).
- The protocol or scheme to prove is specified in a process calculus.
- The prover provides a sequence of indistinguishable games that lead to the proof and a bound on the probability of an attack.
- The user is allowed (but does not have) to interact with the prover to make it follow a specific sequence of games.

Future extensions:

- Extension to other cryptographic primitives, in particular Diffie-Hellman, full support of XOR.
- More game transformations.
- More case studies.

I warmly thank David Pointcheval for his advice and explanations of the computational proofs of protocols. This project would not have been possible without him.

This work was partly supported by the ANR project ARA SSIA FormaCrypt.
